ABSTRACT

Background: The term "biloma" describes a well-demarcated, encapsulated or not, intra-abdominal (extrahepatic or intrahepatic) bile collection outside the biliary tree, secondary to iatrogenic, traumatic or spontaneous rupture of the biliary tree. The clinical symptoms of bilomas are usually nonspecific, ranging from no symptoms to abdominal pain, jaundice, and fever. There were only few cases of huge bilomas in the literature but no report of coincidental extrahepatic and intrahepatic biloma in the same patient.

Case report: We report herein a 12 years boy with huge biloma (20cm in vertical diameter) after blunt abdominal trauma, presented with unique clinical features of marked emaciation and diffuse abdominal distention. To our knowledge this is the largest biloma ever reported in paediatric age group and the first biloma with such unique clinical presentation, and the first case with both extrahepatic and intrahepatic bilomas in single setting.

Conclusion: Although biloma is rare condition but it needs to be considered in differential diagnosis of diffuse abdominal distension in patients following abdominal trauma or surgery.

Keywords: Bile Ducts, Extrahepatic, Intrahepatic, Iatrogenic Disease.
CASE PRESENTATION

A 12 years boy who was involved in a car accident, sustained blunt trauma to abdomen. Emergency laparotomy and splenectomy was performed in a local hospital. The child passed an un-eventful postoperative course and discharged home after one week. One month later he started to complain of abdominal discomfort, anorexia, and wasting. The patient was neglected until referral to our tertiary hospital about 2 months later. He was presented complaining of diffuse abdominal distension and wasting. On examination, the patient was emaciated, pale, no jaundice, with sunken eyes. The abdomen was hugely distended, tense, dull on percussion except on small area in the right side, [Figure 1].

There was a positive thrill and a negative shifting dullness. Bowel sounds were normal. Liver function tests were normal, bilirubin was 1mg/dl. Haemoglobin was 10gm/dl. Chest X-ray revealed abnormally elevated left dome of diaphragm, resulting from huge soft tissue density in the abdomen[Figure2]. Ultrasound examination revealed a huge cystic mass in the abdomen of undetermined origin.

CT scan revealed a homogenous cystic mass extending from the left dome of diaphragm down to the pelvic area (20cm vertical diameter) [Figure 3 A & B]. In addition, CT scan also showed two intrahepatic cystic collections.

A total of 4200 ml of greenish brown, thick fluid with a lot of debris was evacuated, in addition to the fluid that was spilled over and soaked by packs. On exploring the cavity of the cyst, there was no apparent bile leakage from liver surface. After complete evacuation, external drainage by a tube drain was put in a dependent portion of the cavity.

Postoperatively the patient put on intravenous fluids, and parenteral antibiotics. The postoperative period was uneventful; the drainage was 600, 450, 200, and 120 mls during the succeeding days. Oral intake was started at the second postoperative day and the patient discharged home at the 6th postoperative day. At the 8th postoperative day the drainage was only 100 ml, ultrasound examination revealed neither residual collection nor any intrahepatic collections, so the drainage tube removed.

The child was seen 2 months later in good condition with improvement in his nutritional status. Ultrasound examination of abdomen revealed no any pathology in the abdomen.

**DISCUSSION**

The term "biloma" describes a well-demarcated, encapsulated or not, intra-abdominal bile collection outside the biliary tree. Whipple in 1898 was the first to describe a cystic swelling containing bile stained fluid following liver trauma. Gould and Patel in 1979 described an encapsulated bile collection in the right-upper abdominal quadrant following blunt abdominal trauma and called it a "biloma". Bilomas are either intrahepatic or extrahepatic.

Bilomas are mainly caused by iatrogenic or traumatic injuries to biliary passages. However there are few reports of spontaneous bilomas in the literature. Iatrogenic injury to biliary passages following abdominal surgery is the most common cause of biloma. Cholecystectomies whether open or laparoscopic are the main causes of biloma formation.

Also bilomas were reported after liver transplantation and hepatic resections. Blunt abdominal trauma was another important cause of biloma. Its pathogenesis is attributed to either direct disruption of extrahepatic bile ducts, or liver rupture with disruption of intrahepatic bile ducts, or secondary tissue necrosis with bile leakage.

Post-traumatic bilomas have been rarely described in children and are still the subject of isolated case reports. In our child the biloma was developed about 2 months after the trauma, and its pathogenesis can be explained as that of secondary tissue necrosis that lead to bile leakage. The leakage was minor and slowly accumulated over long time within the boundaries of lesser sac forming the huge extrahepatic biloma.
Bilomas usually present with non specific clinical features like abdominal pain, nausea, anorexia, jaundice, fever and abdominal tenderness. However the history of recent surgery or trauma may highlight the suspicion of biloma. In our case, diffuse abdominal distension with marked emaciation was misleading as long as no such clinical presentation was ever reported before. In addition, the history of previous emergency splenectomy pointed to the suspicion of pseudocyst of pancreas as a sequel to iatrogenic injury to the tail of pancreas. For these reasons the definitive diagnosis was unexpected and only made after surgery. Even needle aspiration in our case failed to help in diagnosis because the collection was complicated by blood and the aspirate appeared greenish brown which is not the characteristic appearance of bile. However needle aspiration could be diagnostic in uncomplicated bilomas where the aspirate showing the characteristic appearance of bile cannot provide the definitive diagnosis.

Ultrasonography is helpful in the diagnosis, where Biloma appear as an echo free with acoustic enhancement while CT scan in addition, it can define the cause and relations of bilomas with the adjacent structures more accurately.

In our case the CT scan clearly identified the huge extrhepatic fluid collection, occupying the whole left side of abdomen. Interestingly another two intrahepatic cysts were seen by CT scan, appeared as hypodense lesions inside the liver. Such coincidence of both intrahepatic and extrhepatic bilomas in the same patient was not found in the literature. CT scan and ultrasonography cannot differentiate bile from other fluid collections; like hematoma, seroma, liver abscess, cysts, pseudocysts, and lymphocele and so cannot provide the definitive diagnosis.

However cholescintigraphy by 99mTc-PMT was useful for the accurate diagnosis, as it can demonstrate communications between the injured biliary systems and other spaces very clearly.

Bilomas are liable for complications if left without treatment. Infection and rupture of bilomas into the peritoneal cavity are reported complications that may need aggressive surgical management.

Only small asymptomatic ones that may resolve spontaneously can be followed without a need for intervenison. Percutaneous drainage was an effective form of therapy for extrhepatic biloma that often eliminated the need for surgical drainage.

Percutaneous drainage of the intrahepatic biloma, with endoscopic retrograde cholangiopancreatography and papillotomy led to resolution of the problem in most cases.

Surgery was performed in our patient mainly because of the extraordinary size of biloma thinking that percutaneous drainage may fail to completely sacrifice the problem. In addition the possibility of pseudocyst of pancreas in our case was another reason for resorting to surgical decision. The surgery was successful in resolving the problem without any complications. However the resolution of the intrahepatic bilomas was unexpected and can't be explained as long as neither sphincterotomy nor aspiration was performed for the intrahepatic bilomas.

CONFLICT OF INTEREST

The author declare that there are no conflicts of interest regarding the publication of this manuscript.
